

Database Security

Lock down sensitive data from outside connections

The Business Issue

With each new Version of VISUAL, there are greater enhancements to user security. This is welcomed news for locking down users from accessing sensitive data through the VISUAL application. However, most companies don't realize that this security does not prevent a savvy user from using their VISUAL credentials to access all table data in the database through an outside database connection – regardless of their limitations in the front end of VISUAL.

The Solution

Visual South's SQL Server Security program. An administrator can manually deny rights to certain tables for users, but this is time consuming and painstaking. The VS SQL Server Security program helps an administrator to lock down tables for users all in one step, either giving the ability to deny all tables, or automatically detect user roles and deny all tables outside of that user's known roles.

The Result

Full control and administration of your SQL Server database. Now a company can have full security control over the VISUAL databases, whether they are from the front end application, or the back end report writer or ODBC user. VS SQL Server Security program gives you more robust control of your company's sensitive data.

Works with VISUAL versions 6.5.2 and above; not compatible with SQLBase or Oracle.
